# rootJS

node.js bindings for ROOT 6

*Jonas Schwabe*

Dr. Marek SZUBA

## Contents

## 1. Purpose

**Project Goal** The goal of this project is to create node.js<sup>®1</sup> bindings for ROOT<sup>2</sup>, thanks to which it will become possible to e.g. integrate ROOT into node-based Web applications.

We aim specifically at ROOT 6 because its LLVM-based C++ interpreter Cling offers many advantages over the one available in older ROOT versions.

### 1.1 Required criteria

The bindings should:

- work on Linux
- allow the user to interact with any ROOT class from the node.js JavaScript interpreter
- accept C++ code for just-in-time compilation
- update dynamically following changes to C++ internals
- provide asynchronous wrappers for common I/O operations (i.e. file and tree access)

### 1.2 Optional criteria

The bindings should:

- support the streaming of data in JSON format compatible with JavaScript ROOT
- implement a webserver based on node.js to mimic the function of the Root HTTP server
- work OS independent (i.e. support Mac OS X, Windows, Linux operating systems)

### 1.3 Limiting criteria

The bindings should not:

- add any extending functionality to the existing ROOT framework
- necessarily support previous ROOT versions
- necessarily support future ROOT versions

## 2. Product usage

ROOTjs will be used to create web-applications that can:

- Expose processed data (that might otherwise be hard to access) and then visualize it locally
- Interact with data both stored somewhere accessible for the server or streamed via remote procedure call (RPC)
- Run on any platform that supports a browser

### 2.1 Audience

Most users of ROOTjs will be competent in Linux and web servers. They will be able to install ROOT, and also proficient in programming languages like Javascript and C++.

- Scientists (e.g. particle physicists)
- Researchers
- Web-developers interested in creating applications based on ROOT

### 2.2 Operating conditions

ROOTjs will be used on servers that run ROOT and have access to the required data sources. As ROOT6 currently runs on Linux and OS X only, usage of the bindings is limited to those platforms.

## 3. Product environment

**Providing ROOT to node.js** Node.js bindings for ROOT simplify the creation of server-client based ROOT applications. The bindings offer solutions based on state of the art web technology, especially the separation of data processing and visualization.

### 3.1 Software

#### 3.1.1 ROOT

ROOT is a software framework for data analysis and I/O. It may be used to process and especially visualize big amounts of scientific data, e.g. the petabytes of data recorded by the Large Hadron Collider experiments every year. Since the framework comes with an interpreter for the C++ programming language, for rapid and efficient prototyping and a persistency mechanism for C++ objects, ROOT based applications are extensible and as feature rich as the C++ language itself. A detailed introduction to the ROOT framework may be found in the *ROOT primer*<sup>1</sup> on the CERN website.

Interfacing with ROOT is done dynamically, since ROOT shares all the necessary information on its (global) functions during runtime.

#### 3.1.2 Node.js

Node.js is an open source runtime environment. node.js is used to develop server-side web applications and may act as a stand alone webserver. It uses the Google V8 engine to execute the Javascript code.

The Binding API to be developed will be a so called native node.js module written in C++. It interfaces directly with the V8 API to provide (non-blocking) encapsulation of ROOT objects as Javascript equivalents.

### 3.2 Hardware

Since the Bindings, in simplified terms, just provide data structures for encapsulation of ROOT objects or rather functions, the hardware requirements of the bindings themselves should be negligible.

Basically calling a ROOT function via the Binding-API inside a node.js application really should not take up a huge amount of additional resources compared to a direct function call inside a native ROOT application. In conclusion there are no additional hardware requirements for using the Bindings on a computer that was able to run native ROOT applications before - this includes almost any modern Desktop PC.

## 4. Product interface and functions

The RootJS bindings do not have a usual interface, there will neither be a graphical user interface nor a command line interface. This section will therefore specify the application programming interface.

/I10/	The module will expose a JS object containing all accessible root variables, functions and classes
/I20/	Exposed variables might contains scalar values, in this case they will be accessible in their JavaScript counterparts
/I30/	Exposed variables might be objects, these objects are recursively converted to JavaScript objects until there are only scalar values
/I40/	Exposed variables might be enums, in this case the identifier of the currently selected value is returned, insted of the corresponding integer
/I50/	Every exposed method will be accessible via a proxy method which handles parameter overloading, as JavaScript does not support overloading, an Exception will be thrown if there is no method to handle the passed arguments
/I55/	A method can be called with an additional callback method that will be called after the method ran
/I60/	Exposed classes will be accessible as a construction method, returning the object, the construction method will be proxied in order to support parameter overloading, an exception will be thrown if there is no method to handle the passed arguments
/I65/	A constructor can be called with an additional callback method that will be called after the object has been constructed
/I70/	The classes are encapsulated in their namespaces from root. Each namespace is an Object containing namespaces, or class constructors
/I80/	Exceptions thrown by Root will be forwarded to JavaScript and can be handled the usual way
/I90/	Global variables are accessible via getter and setter methods to ensure their values are kept in sync with the ROOT framework
